PUERAPERAL STREPTOCOCCUS PNEUMONIAE ENDOMETRIC - A CASE REPORT AND LITERATURE REVIEW

Fatma R. Hajiyeva

Abstract
Streptococcus pneumoniae endometritis is an exceedingly rare clinical occurrence in the immuno competent individual. This case report describes such an occurrence in an otherwise healthy woman 39 days post-normal vaginal delivery. The patient responded to prompt broad-spectrum intravenous antibiotics and made a full recovery. The clinical relevance of such a scenario, the likely pathogenesis of the event as well as a brief review of relevant clinical literature are discussed.

Keywords
endometritis, female, puerperal infection, Streptococcus pneumonia, Raman spectroscopy

Introduction
Streptococcus pneumoniae genital infection was a well-documented clinical entity in the pre-antibiotic era with a high mortality rate - 26% for localised infection and 74% for peritonitis and sepsis. More recently, however, there have been only isolated reports of Streptococcus pneumoniae genital infection, with even less frequent accounts of this happening in immuno competent individuals. In this report, we document a case of Streptococcus pneumoniae endometritis in a young, previously healthy female 39 days post-partum.

Case Report
The patient, a 24 year old, dyslipidaemic gravida 4, para 3, was electively admitted to the Research Institute of Obstetrics and Gynecology for induction of labour at 38+4 weeks of gestation due to intra-uterine growth retardation (IUGR); investigation prior to induction had revealed no obvious cause for the IUGR. Following two doses, 12 hours apart, of 1mg topical prostaglandin E2 (Prostin E2®) placed in the posterior fornix of the vagina, and nine hours after artificial rupture of membranes, she delivered an apparently healthy boy weighing 2.23 kg of Apgar scores 9 and 9 at one and five minutes, respectively. She enjoyed an uneventful postnatal period, and mother and son were found fit for discharge 48 hours after delivery.

She presented again 39 days later with a short history of severe, colicky epigastric and suprapubic pain radiating to the back. The pain was associated with chills, rigors and two episodes of vomiting.

Physical examination revealed a distressed patient with a temperature of 38.5°C, a blood pressure of 123/63mmHg, and a heart rate of 80 beats per minute. Her abdomen was tender on deep palpation suprapubically and in both flanks, with minimal signs of peritonism. Pelvic examination showed moderate cervical excitation, mild right-sided adnexal discomfort and a yellowish vaginal discharge. High vaginal and endocervical charcoal swabs were taken.

To enhance the technologies available for monitoring and control of some parameters in bioreactors, several optical and spectroscopic modalities have been investigated as they are non-invasive and provide information in real time. Raman spectroscopy is one of the most promising techniques in this regard. It is based on the inelastic scattering of light and provides a biochemical fingerprint for the sample under investigation. High chemical specificity of Raman spectroscopy is the result of its measurement of vibrational energies in chemical bonds.

Raman spectroscopy coupled with chemometrics has recently been used for real time monitoring and simultaneous prediction of multiple culture parameters including glutamine, glutamate, glucose, lactate, ammonium, viable cell density, and total cell density culture bioreactors. It has also been used for the rapid identification, characterization, and quality assessment of complex cell culture media components used for industrial mammalian cell culture. But, all of the studies have used implicit models, where reference measurements on a training sample set are performed to acquire information about the system to be investigated. A model is thus constructed, based on the training set, which implicitly accounts for any physical effects that influence the measured Raman spectra, allowing concentration estimation of unprocessed samples. However, the training samples are system specific and only model the particular system under investigation.

Short description of spectroscopy: Raman scattering studies were carried out on a three-dimensional confocal Raman microspectrometer Nanofinder 30 (Tokyo Instr.), Excitation wavelength λ = 532 nm. The radius of the cross section of the incident laser beam was approximately 4 μm. The investigations were carried out in the geometry of

1 Research Institute of Obstetrics and Gynecology Ministry of Health of Azerbaijan Republic
backscattering. The radiation receiver was a cooled CCD camera (-70°C) operating in the photon counting mode. All measurements are taken at an exposure time of 1 second and an excitation radiation power of 8 mW (mWt). The accuracy of determining the position of the spectral line was not worse than 0.5 cm⁻¹.

Three hours after presentation, her blood pressure dropped to 91/55 mmHg. Arterial blood gas examination performed at the time of this haemodynamic deterioration revealed a pH of 7.39, pO₂ of 86.5 mmHg, pCO₂ of 36.0 and a lactate level of 2.8. Peripheral blood studies revealed a leucocytosis with neutrophil shift; inflammatory markers - erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) - were found to be raised. Amylase was normal and urine and peripheral blood cultures were eventually returned negative.

The patient was initially admitted to a surgical bed; intravenous antibiotic was commenced.

Computed tomography scanning of her abdomen revealed an enlarged uterus with oedematous changes in the uterine wall and free fluid in the pouch of Douglas. She was transferred to a gynaecological bed. Treatment remained unchanged. Symptomatic improvement and gradual normalisation of ESR and CRP were seen and piperacillin-tazobactam was changed to oral coamoxiclav (Augmentin).

A pure culture of mucoid, Gram-positive diplococci with lanceolate morphology was obtained from the patient’s endocervical swab. The presence of Streptococcus pneumoniae was confirmed by showing draughts man colonies with weak-haemolysis on horse blood agar, sensitivity to ethyl hydrocuprein (optochin), and bile solubility. The presence of a polysaccharide capsule was confirmed by using the Phadebact Pneumococcus Co-agglutination test. The isolate was sensitive to penicillins, macrolides and newer generation fluoroquinolones.

A final diagnosis of puerperal S. pneumoniae endometritis was made.

After five days of oral antibiotic treatment, the patient was discharged home on a further 3 days of antibiotics. She remained well at an outpatient appointment followup 4 weeks later.

Discussion

In the pre-antibiotic era, S. pneumoniae not infrequently caused female genital tract infections as a consequence of septic abortion, instrumental vaginal delivery and metastatic seeding of pneumococcal septicaemia. However, primary pneumococcal infection of the female genital tract, as documented in this case scenario is, nowadays, an extremely rare occurrence.

Pneumococci are not components of normal vaginal flora: in a literature review in 1990, Westh et al. described three studies where pneumococci were only cultured from 9 genital isolates out of a total of 1715 patients (0.5%) while a further three microbiological studies gave no mention whatsoever of pneumococcus isolates from the female genital tract. It is thought that pneumococci are unable to survive at normal vaginal pH; although it is postulated that changes in vaginal pH, as for example during pregnancy and the puerperium, may temporarily allow S. pneumoniae to exist as a vaginal commensal.

Risk factors for pneumococcal infection include antibody and complement deficiency, asplenia, neutropenia or impaired neutrophil function, steroid therapy, malnutrition, alcoholism, chronic medical conditions (renal failure, liver failure, heart failure, and respiratory pathology) and overcrowding. The organism possesses a number of virulence factors that aid in the pathogenesis of infection:

1. Polysaccharide capsule - prevents opsonisation and phagocytosis. Different serotypes exhibit different severity of infection.
2. IgA protease - cleaves IgA1 and enables evasion of the protective function of this immunoglobulin isotype.
3. Pneumolysin - an intracellular membranedamaging toxin released by autolysis. It serves to inhibit neutrophil chemotaxis, phagocytosis and respiratory burst, lymphocyte proliferation and immunoglobulin synthesis.
4. Autolysin - breaks the peptide cross-linking of the cell wall resulting in cell lysis and release of pneumolysin as well as cell wall fragments.

Most reports on pneumococcal female genital tract infections with or without secondary pneumococcal peritonitis suggest three possible mechanisms by which pneumococci can infect the genital tract or peritoneum. These include:

- Infection via the external genitalia - following a change in vaginal pH, it is thought that S. pneumoniae can exist as a commensal. Pneumococcal Bartholinitis has been described as have ascending infections. The presence of an intrauterine device, instrumentation of the uterine cavity, the use of tampons and the puerperal period are all thought to facilitate ascending infection from the vagina.
- Infections via the bloodstream - this is exceedingly uncommon nowadays and is associated with a high mortality (presumably secondary to metastatic pneumococcal infection and septicaemia and not specifically to genital tract involvement)
- Infection following orogenital sex - pneumococci are known commensals of the oropharynx and it has been postulated that orogenital sex can cause pneumococcal and Haemophilus influenzae genital tract colonization and possibly infection. Paradoxically, Pitroff et al. in 2012 suggested that oral sex might actually be protective and decrease the risk of endometritis. Infection via the gastrointestinal tract and via transdiaphragmatic lymphatics have also been suggested as mechanisms of infections but a literature search yielded no evidence confirming these theories.

Fernandez et al, in a 1993 prospective study on 1291 patients, suggested that a single 1.2g intra-venous dose of co-amoxiclav at the onset of labour would decrease the risk of postpartum endometritis and also be cost effective. While a comprehensive 2007 article on puerperal pyrexia by Maharaj suggests that high risk patients (those with previous spontaneous preterm delivery, history of low birth weight, pre-pregnancy weight less than 50 kg, or bacterial vaginosis in the current pregnancy) might benefit from prophylactic antibiotics in the second and third trimester of pregnancy, the author stops short of recommending the routine use of prophylactic antibiotics against postpartum endometritis.

A 2007 Cochrane review of antibiotic choices for the treatment of established post-partum endometritis recommends the use of intravenous clindamycin and a
once-daily dose of gentamicin, with no benefit seen with further oral antibiotics once clinical improvement is sustained for more than 24 hours; this recommended combination was not used in this scenario due to a delay in diagnosis. The rationale behind these recommendations is based on the sensitivities of the commoner causative organisms of puerperal endometritis. Although S. pneumoniae endometritis is a highly uncommon aetiological agent for post-partum endometritis, no change to usual clinical practice is needed in view of the fact that an intravenous clindamycin-gentamicin combination would appropriately treat this rare scenario.
